

Geostatistical Analysis

ISTANBUL **TECHNICAL** UNIVERSITY

Sp. Anly. and Alg. in GIS
Week 10

Res. Assist. Ömer AKIN

Introduction & Aim of the Study

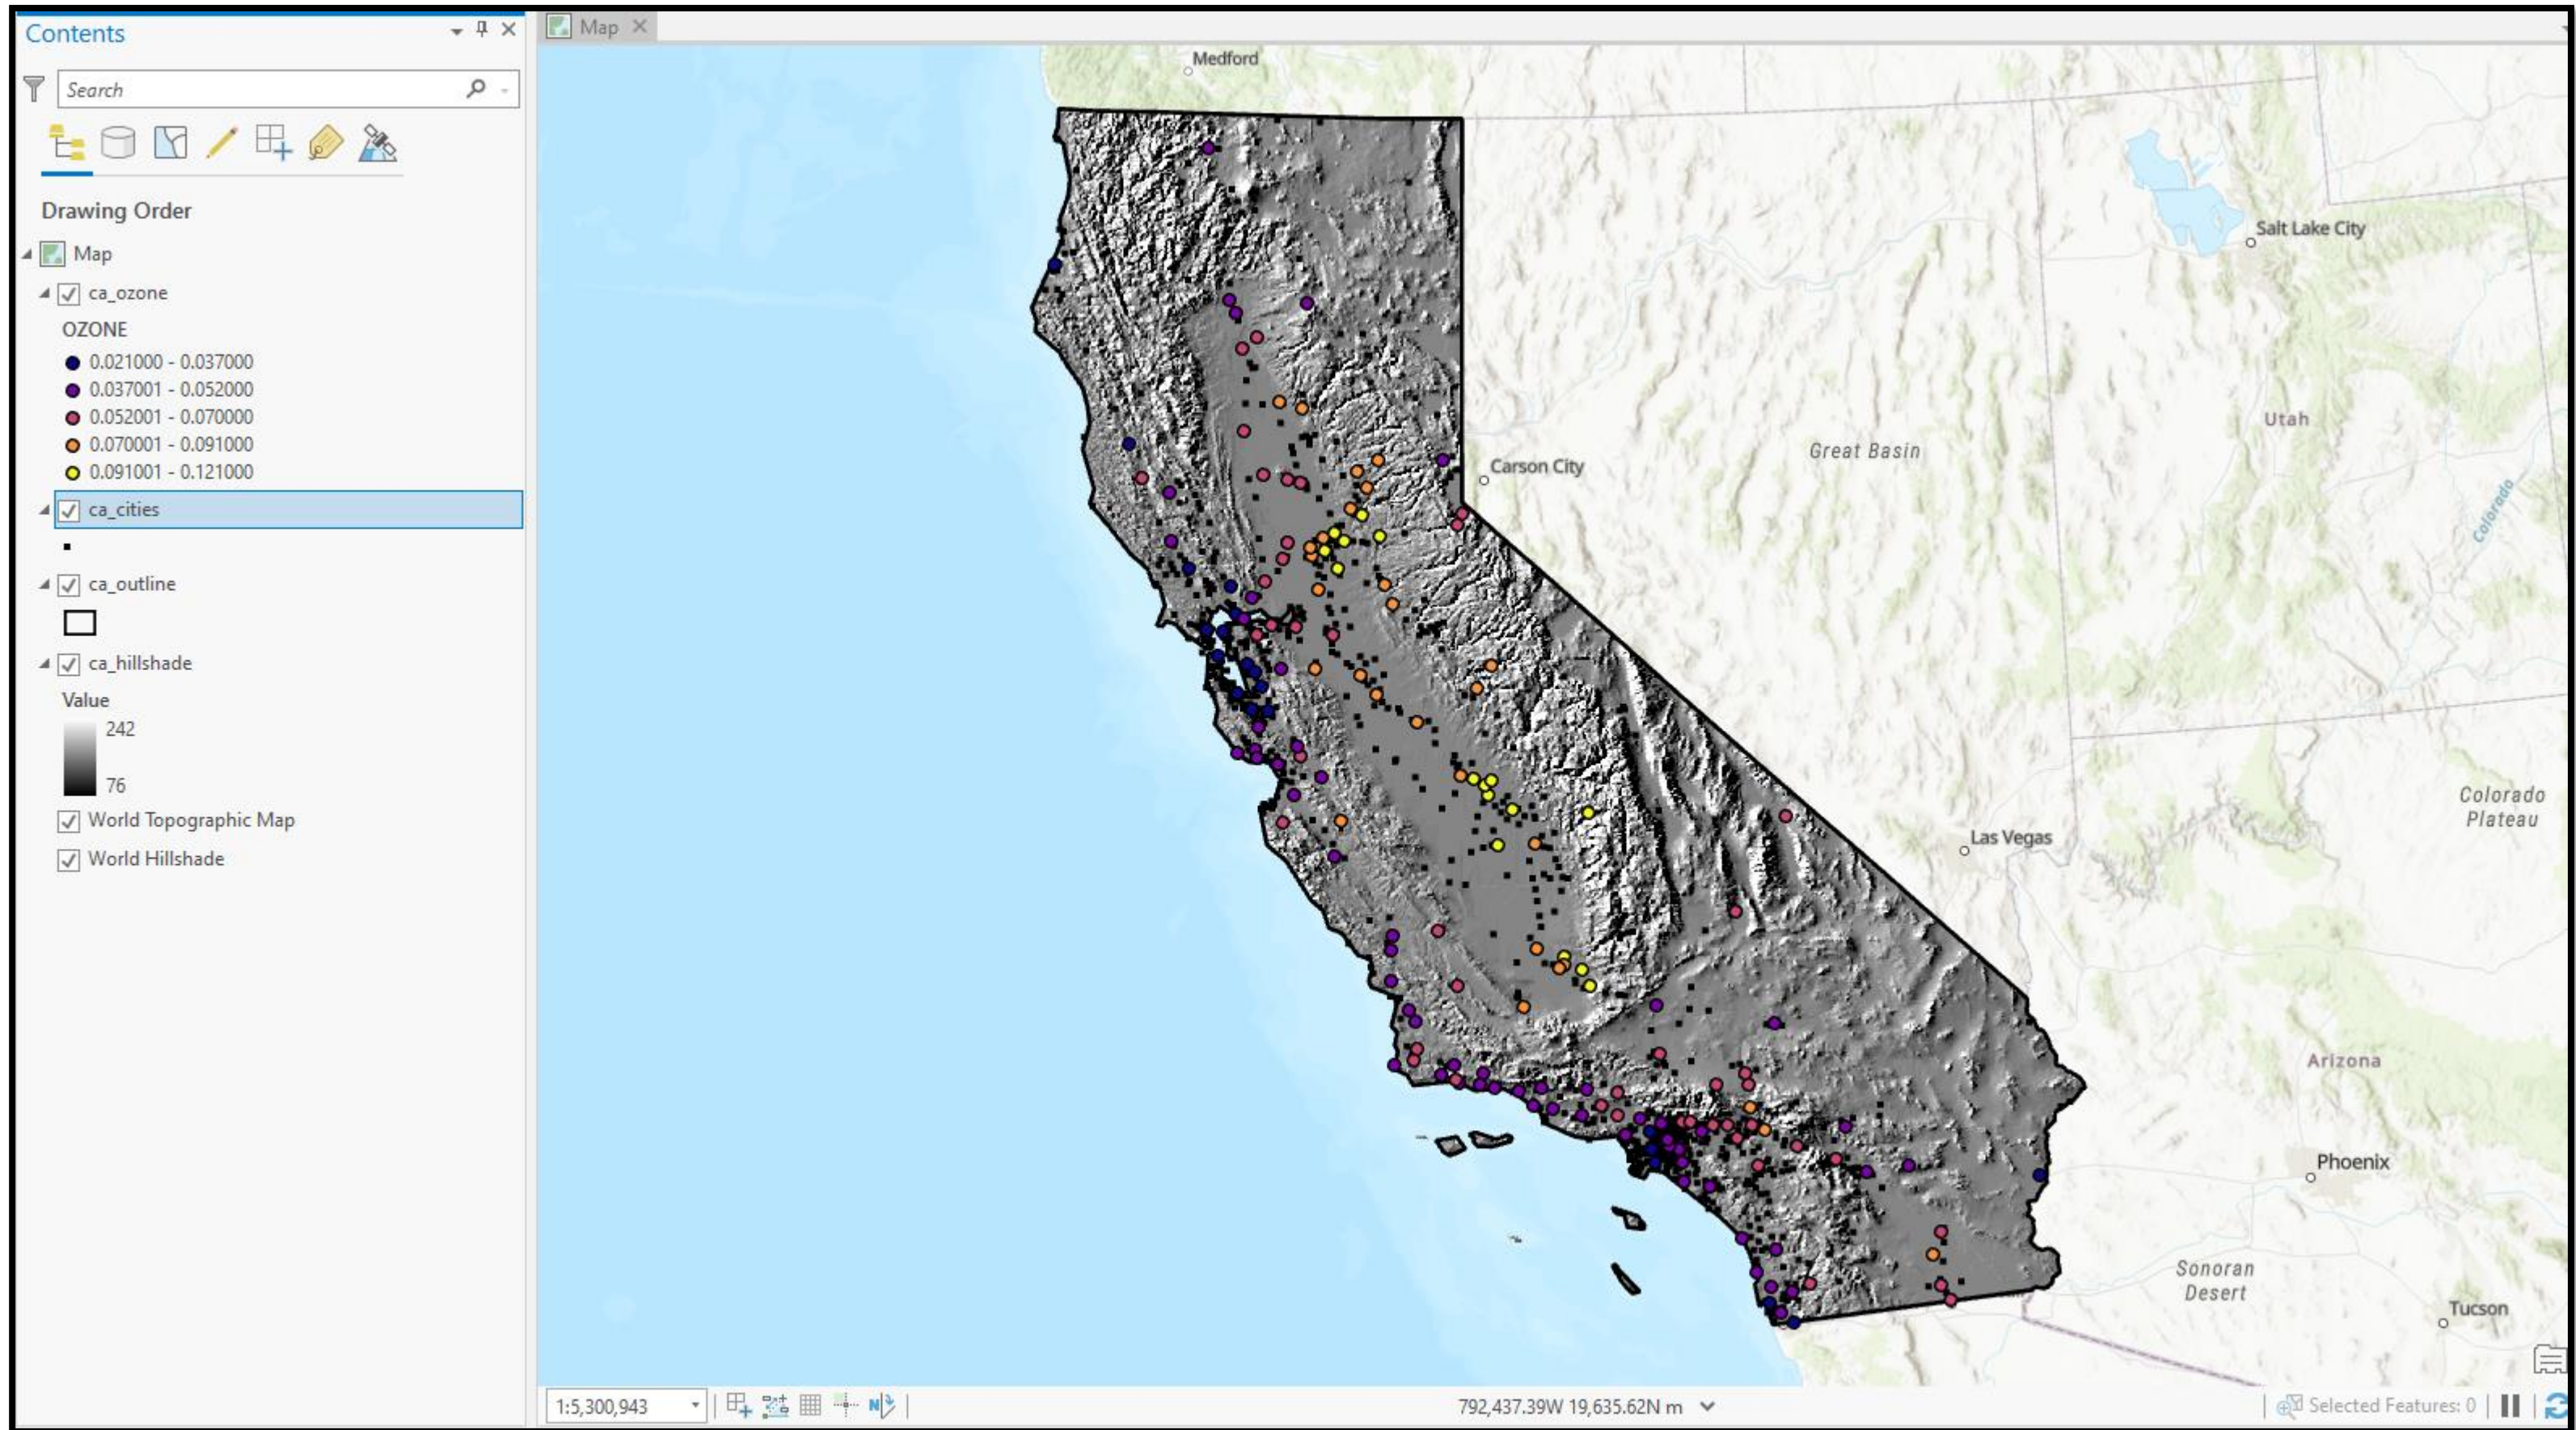

Aim of the Study:

- *Ozone concentration is measured at monitoring stations throughout the state of California. The locations of monitoring stations and concentration levels of ozone are known for all the stations, but the ozone values for other (unmonitored) locations in California are also of interest.*

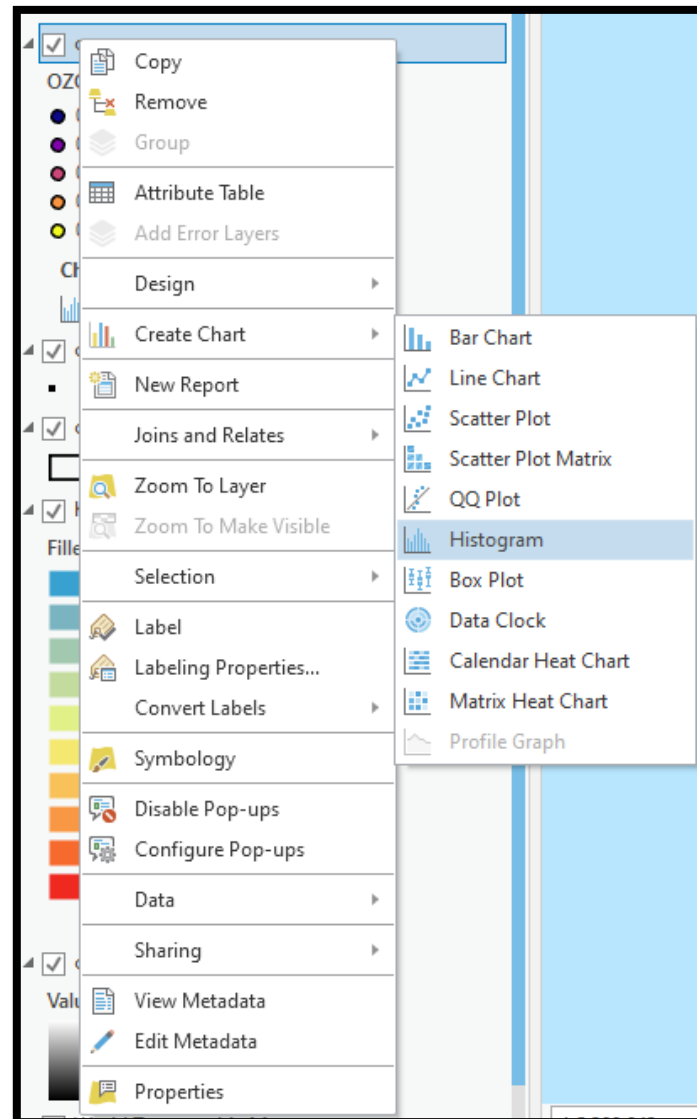

Input Data:

- *Ozone Concentration (measured on September 6, 2007 between 3:00 and 4:00 p.m.) (Vector-Point)*
- *City Centers (Vector-Point)*
- *Border of California (Vector-Polygon)*
- *Hillshade (Raster)*

Study Area & Data

Explore Data Statistics

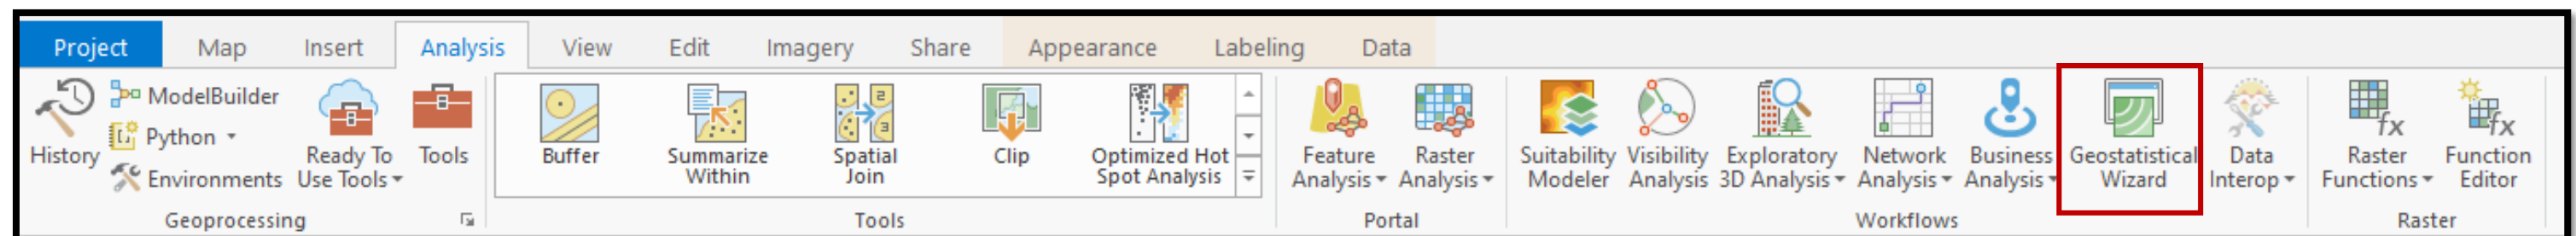

Statistics	
	Dataset
<input checked="" type="checkbox"/> Mean	0.0589730539
<input type="checkbox"/> Median	0.056
<input type="checkbox"/> Std. Dev.	0.0211534025
Count	167
Min	0.021
Max	0.121
Sum	9.8485
Nulls	0
Skewness	0.7042560409
Kurtosis	2.8320571739

- As a quick check, if the mean and the median are approximately the same value, you have one piece of evidence that the data may be normally distributed.
- The ozone data histogram indicates that the data is unimodal (one hump) and skewed right. The right tail of the distribution indicates the presence of a relatively small number of sample points with large ozone concentration values. It seems that the data is not close to a normal distribution.

Geostatistical Analyst

Geostatistical Analyst provides tools that make optimal predictions possible by examining the relationships between all the sample points and producing a continuous surface of ozone concentration, standard errors (uncertainty) of predictions, and probabilities that critical values are exceeded.

Geostatistical methods

Kriging / CoKriging

Kriging is the oldest and most studied geostatistical interpolation method. It is very flexible and allows you to investigate graphs of spatial auto- and cross-correlation. Kriging uses statistical models that allow a variety of output surfaces including predictions, prediction standard errors, probability, and quantile. The flexibility of kriging can require a lot of decision-making. Kriging assumes the data come from a stationary stochastic process, and some methods assume normally-distributed data.

Semivariogram/Covariance Model

- The semivariogram/covariance model is displayed, allowing you to examine spatial relationships between measured points.
- You can assume that things that are closer together are more alike than things that are farther apart. The semivariogram allows you to explore this assumption.
- The process of fitting a semivariogram model to capture the spatial relationships in the data is known as variography.

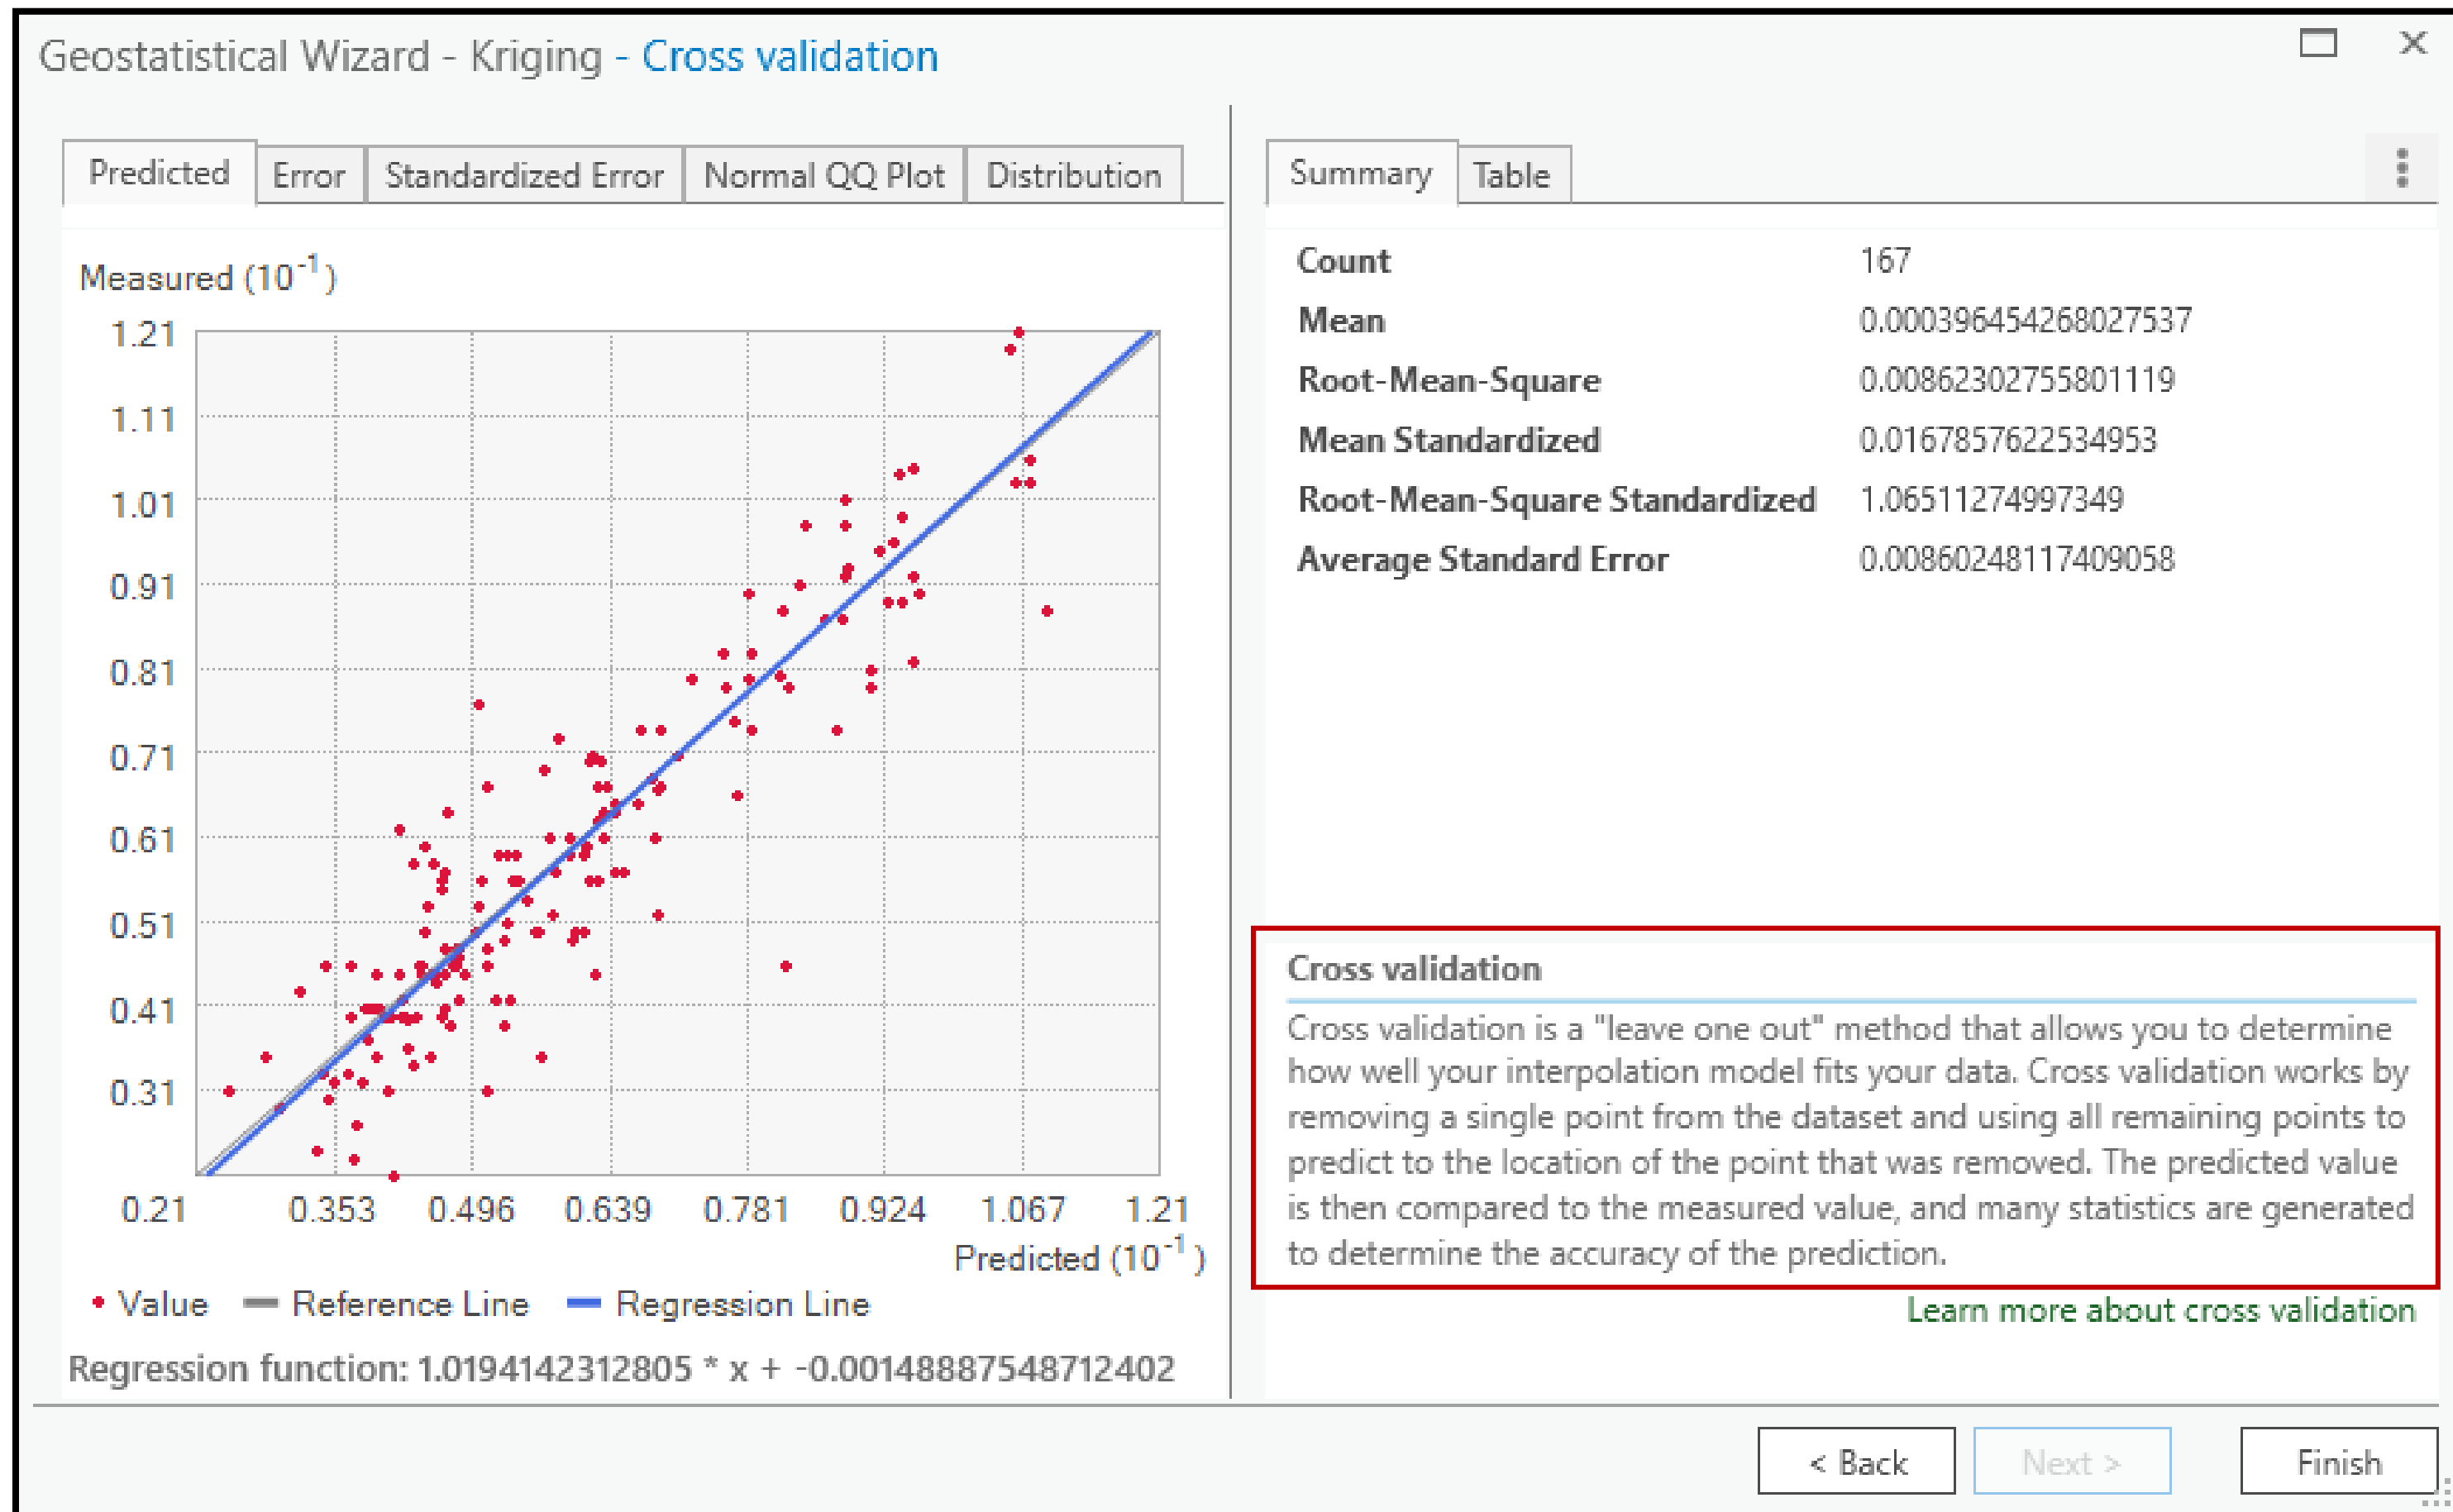

Prediction Surface

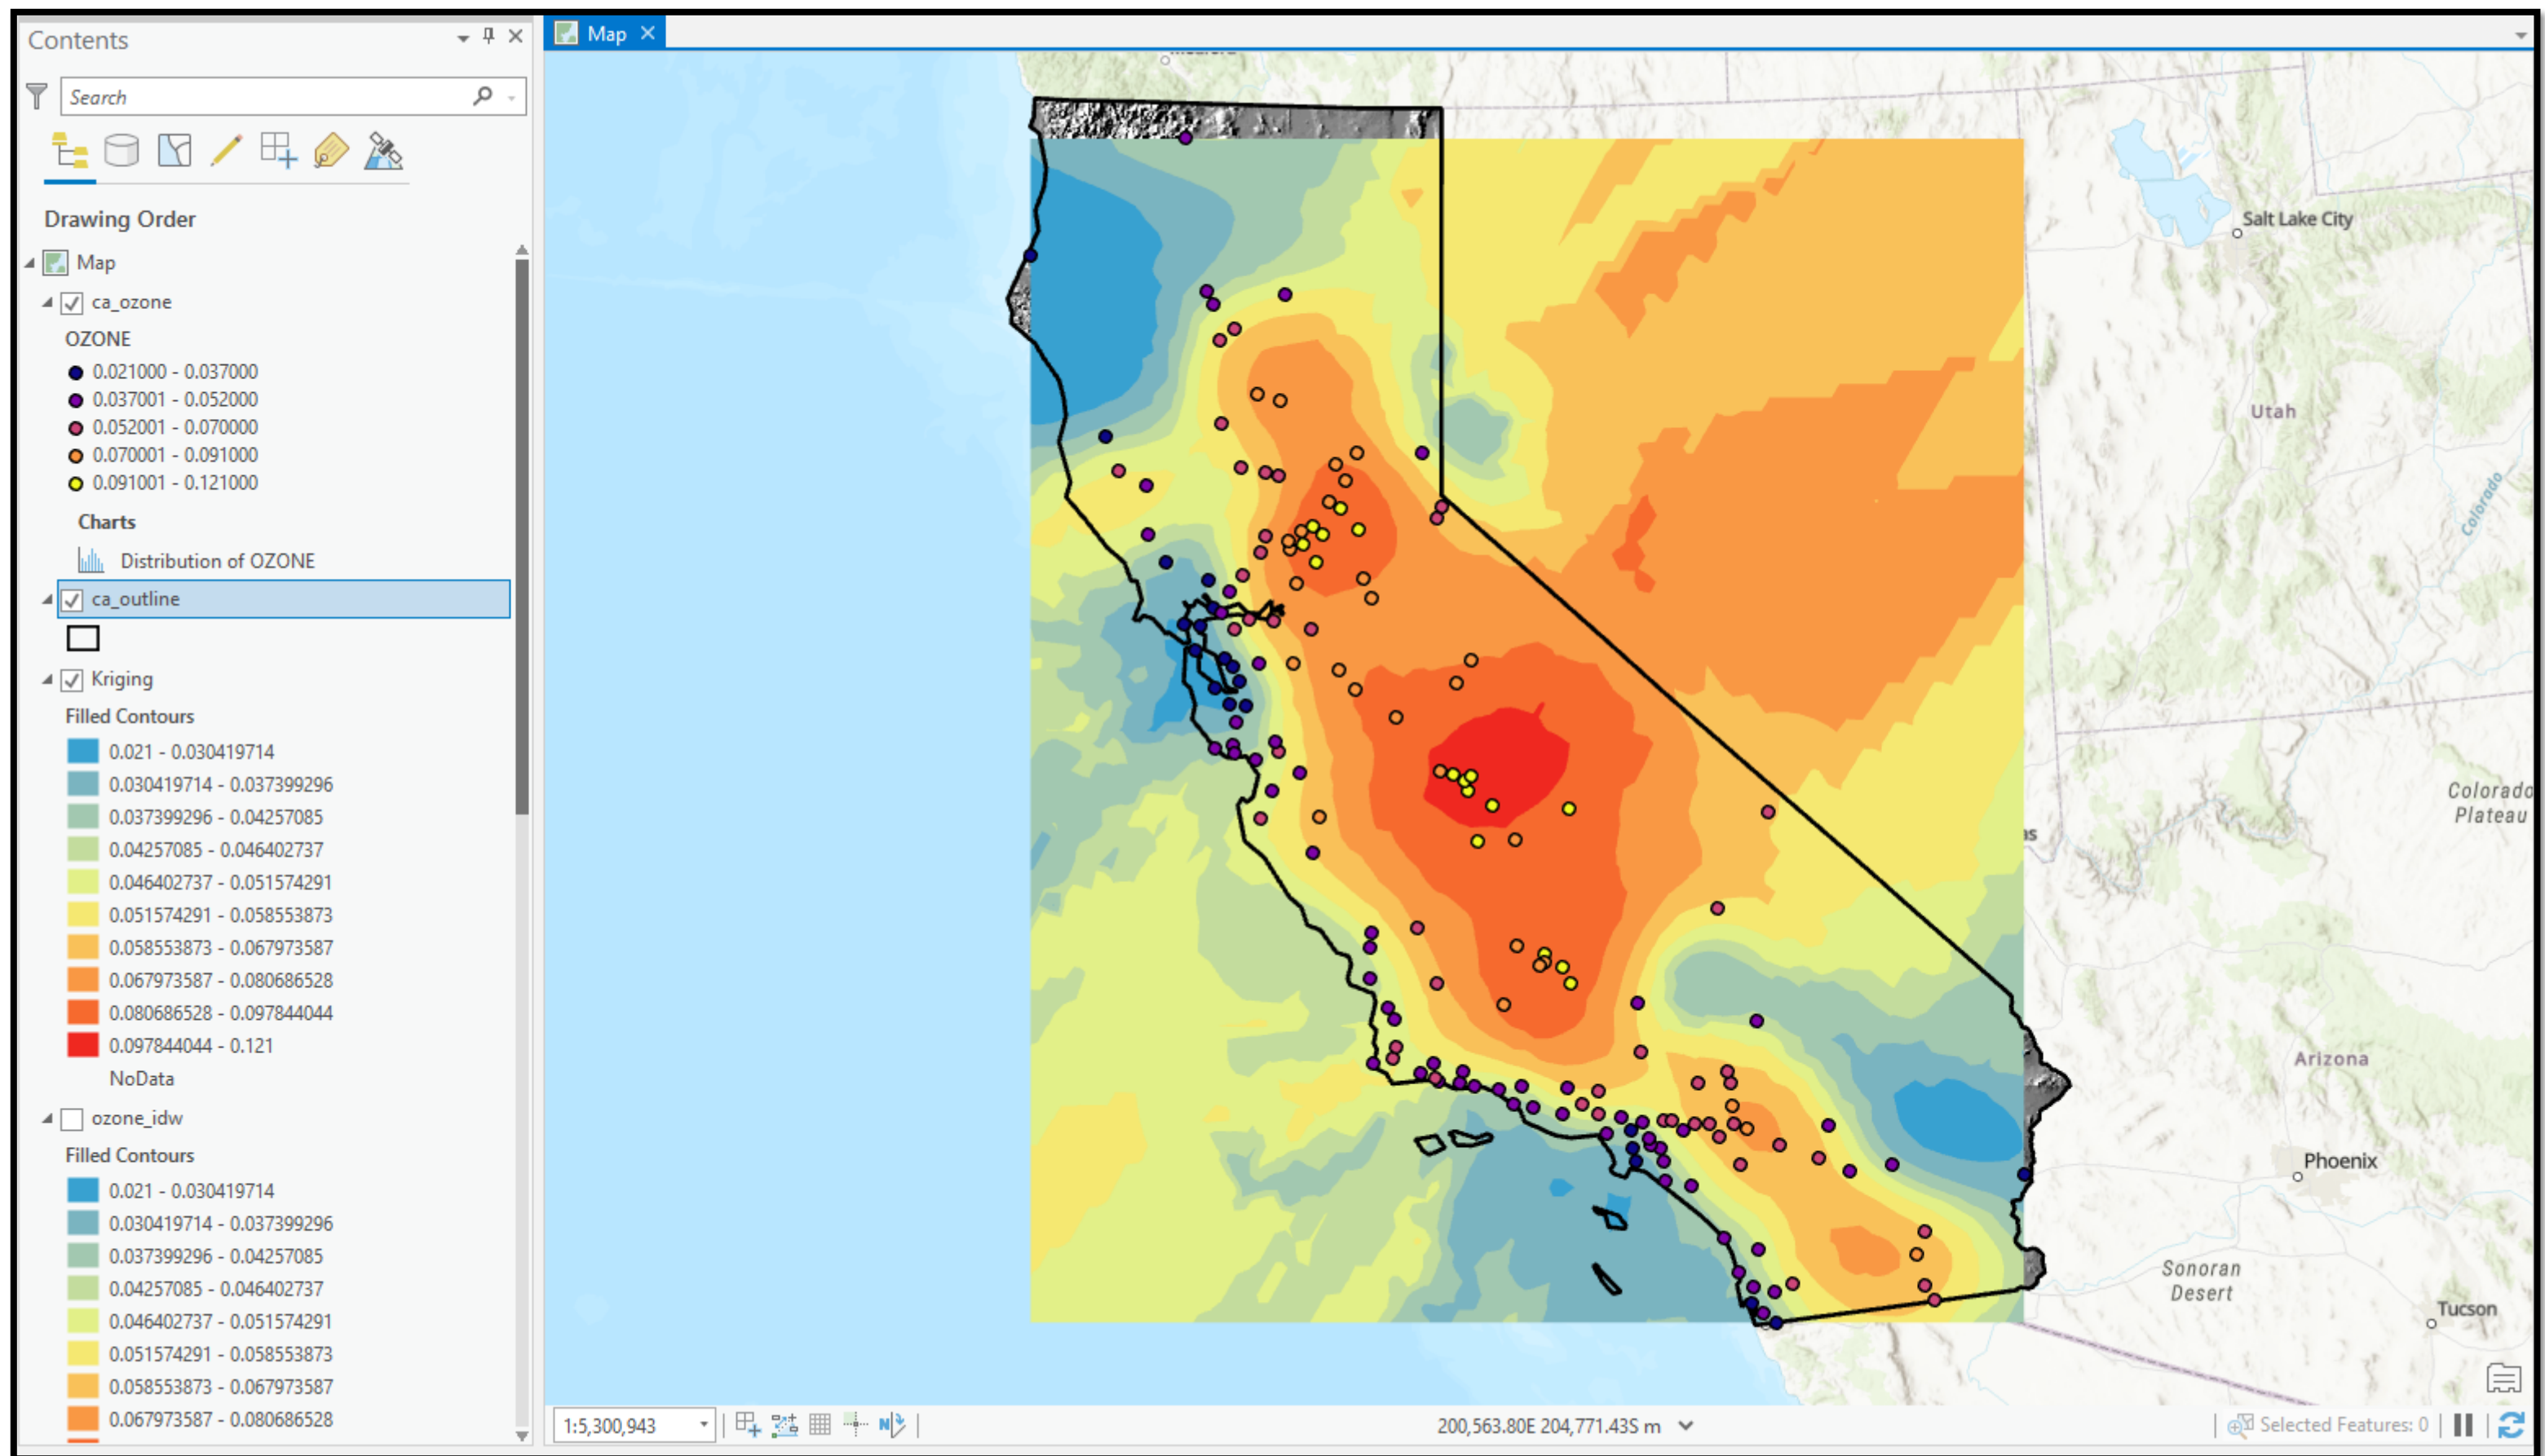

- As shown, the values of the closest measured locations are most alike to the value of the unmeasured location that you are trying to predict.
- The red points in the image below are going to be weighted (or influence the unknown value) more than the green points since they are closer to the location you are predicting.
- Using the surrounding points and the semivariogram/covariance model fitted previously, you can predict values for the unmeasured location.

Inverse Distance Weighted (IDW)

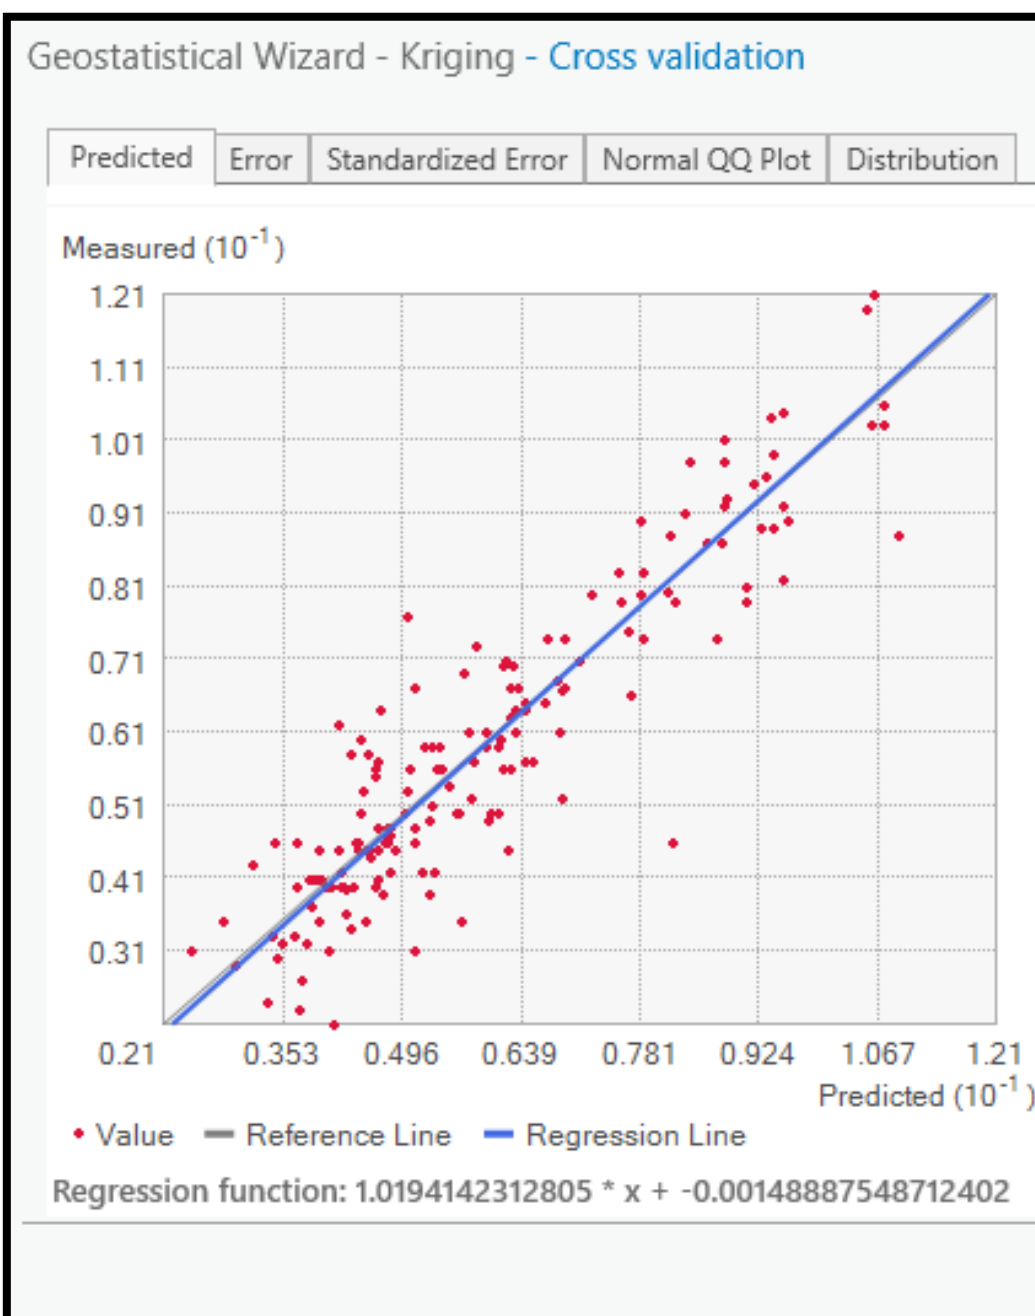

- Inverse distance weighted (IDW) interpolation explicitly makes the assumption that things that are close to one another are more alike than those that are farther apart.
- To predict a value for any unmeasured location, IDW uses the measured values surrounding the prediction location.
- IDW assumes that each measured point has a local influence that diminishes with distance. It gives greater weights to points closest to the prediction location, and the weights diminish as a function of distance, hence the name inverse distance weighted.
- Weights are proportional to the inverse of the distance (between the data point and the prediction location) raised to the power value p . As a result, as the distance increases, the weights decrease rapidly.
